This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1902 Excerpt: ...point in the system; thus: point B describes a circle around point A, and, at the same time, point E describes a circle around point B. Four positions of points B and E are shown by full lines, and dotted lines indicate the positions E would take if it did not revolve about B; in which case the cut-off valve would evidently not slide on the main valve at all, and there would be no cut-off action. This action, therefore, depends on the rotation of E around B, and is not in the least effected by motion of B Fig-55-about A; and the relative motion of the cut-off valve will be as if it worked on a stationary seat, and was driven by an eccentric of eccentricity equal to distance B E. The upper circle, Fig. 55, represents the path of this equivalent ideal cut-off eccentric, and corresponding and coincident positions of the eccentrics in both figures are indicated by the notation. Note that corresponding positions of the cutoff eccentric arm, from B as a center of rotation in both figures, are parallel. When the equivalent eccentric is at mid-throw the cut-off valve is in its central position relative to the mainFig. 56. valve, and if the cut-off edges were then "line and line," the cut-off action would evidently be the quickest possible; and the fallacy of the common statement that the quickness of the cutoff is due to the fact that main-and cut-valve move in opposite directions, becomes evident, for, as in the present case, the cut-off may become quicker if the main valve does not move at all. The superiority of the independent cut-off lies in the facts that no restriction of the main port-opening is required, and that the cut-off may occur when the virtual, or equivalent, cut-off eccentric is near the middle of its throw. 1 The independent cut-off act...
